Hot landscape sites require special consideration before trees are planted. Trees can survive, and even thrive, in hot sites if the site is prepared correctly, if heat-tolerant species are selected, and if the trees are properly maintained. A variety of different locations and situations qualify as hot landscape sites.

Hot site locations

• Because of large masses of asphalt and concrete that absorb and reflect heat, urban areas tend to be an average of 9° F to 12° F warmer than surrounding wooded areas. Buildings and roads cool slowly, so heat continues to radiate even after sunset — an effect called the "urban heat island."

The foremost Norway maple is nearest the paving and as a result has scorched leaves.

 Areas adjacent to buildings also tend to be hot. Buildings reflect heat onto trees, especially along southern and western walls

Heat reflected from the building has scorched the leaves of this linden.

• Sites near roads and parking lots are hot. The temperature of automobile surfaces can exceed 122° F during the summer. When combined with the heat from car fumes and the temperature of asphalt and concrete, these sites can be lethal for trees.

The foreground tree is dying because it is planted in a small volume of hot, dry soil in a parking lot.

- Underground
 utilities can also create hot sites. Soils around certain
 utilities, such as steam lines, can be significantly hotter than adjacent soils.
- Containers and raised beds become hotter than inground planting areas. Where soil is above ground level and uninsulated by surrounding soil, sites are subject to greater extremes of heat and cold.
- Open areas, such as fields and parks, are typically hotter than wooded areas where trees provide shade for each other and the surrounding soil. Leaf litter on the ground in wooded areas keeps the soil cooler, as does mulch in open, unshaded landscapes.

Dogwoods planted in hot, unshaded areas are more likely to suffer heat damage than...

...dogwoods planted in their natural habitat – shaded, wooded areas.

Why heat is a problem for trees

High temperatures have a detrimental effect on tree leaves and roots. Increased leaf temperatures cause trees to cool themselves through the process of transpiration. As temperatures rise, water vapor is released through small pores (stomata) in the leaf surface, thereby cooling the tree. On a hot day, a large deciduous tree can transpire as much as 100 gallons of water into the surrounding air. This volume of water is not always available to trees on hot sites because of inadequate moisture in the soil. A lack of available water to trees in hot sites often results in scorched (dried) leaf margins or dead leaves.

Scorched leaves on a flowering dogwood grown in full sun.

Preparing hot sites for planting

To help trees adjust to hot sites, preparation prior to tree planting is important. If large planting beds will be used, organic matter such as compost can be incorporated into the soil to improve soil structure, air movement and water retention. Incorporation of organic matter into the backfill soil for individual planting holes is not recommended. Installation of an irrigation system may be beneficial because irrigation can supply water for transpirational cooling.

Selecting trees for hot sites

Trees that are genetically capable of tolerating high temperatures should be selected for hot sites. Some species of trees are naturally heat-resistant, and many cultivars are available that have been developed for their ability to withstand high temperatures. Consideration should be given to site moisture levels because some trees can withstand heat only when adequate moisture is available.

Maintaining trees on hot sites

After heat-tolerant trees have been planted, additional maintenance is needed to ensure long-term tree health. Irrigation can be critical. Trees should receive 1" of water per week during the growing season to replace water lost through transpiration. Water deeply and include areas beyond the tree's dripline (crown spread) where small absorbing roots are located.

Mulching is also very important. Maintain a 2 - 4" layer of mulch over as much of the tree's root zone as possible. Mulching will help keep the soil surrounding the roots cooler, prevent moisture evaporation and water runoff, minimize competing weed growth, and reduce the amount of light and heat that reflects onto leaf and stem surfaces. Remove competing vegetation (weeds, grass) frequently to improve tree survival.

Fertilize trees in hot sites only as needed. Nitrogen causes trees to grow quickly, and an extra flush of new leaves may wilt and die due to heat stress. Do soil testing and observe plant health to determine if and when supplemental fertilization is needed.

Prune trees as necessary to remove broken, diseased, damaged or leggy growth. Pruning improves overall tree health, reduces water demand, and decreases the amount of water that is lost due to transpiration.

In summer, shade newly planted trees with netting or boards until their roots become established and capable of absorbing adequate water for transpiration. Leaves on trees transplanted during summer heat, or into hot sites, are sometimes sprayed with antitranspirants to prevent excessive water loss. In extreme heat, leaves are even stripped from trees to combat desiccation.

Trees for hot sites

Trees for hot sites		
Common Name	Latin Name	Cultivars and Comments
Trident maple	Acer buergeranum	Tough, pest-resistant
Hedge maple	Acer campestre	Tolerates drought
Norway maple	Acer platanoides	'Summer Shade'
Red maple	Acer rubrum	Tolerates urban conditions
Sugar maple	Acer saccharum	'Green Mountain' and 'Legacy', but not
		for Southeastern Virginia
Freeman maple	Acer x freemanii	'Armstrong Two'
Red horsechestnut	Aesculus x carnea	'Briotii'
River birch	Betula nigra	Provide irrigation
White birch	Betula platyphylla	'Whitespire' resists borers
Shagbark hickory	Carya ovata	Very adaptable
Common hackberry	Celtis occidentalis	Tough, wind-tolerant
Cockspur hawthorn	Crataegus crusgalli	Tolerates drought
Washington hawthorn	Crataegus phaenopyrum	Tough, thorny
Japanese cryptomeria	Cryptomeria japonica	Evergreen
Leyland cypress	x Cupressocyparis leylandii	Evergreen; avoid wet areas
Hardy rubber tree	Eucommia ulmoides	Tolerates urban conditions
White ash	Fraxinus americana	Tolerates drought
Green ash	Fraxinus pennsylvanica	Tough, wind-tolerant
Ginkgo	Ginkgo biloba	Select male trees
Honey locust	Gleditsia triacanthos	Tough, tolerates poor soil; 'Shademaster'
Tioney Toolast		is thornless
Chinese juniper	Juniperus chinensis	Evergreen; 'Spartan'
Rocky mountain juniper	Juniperus scopulorum	Evergreen; 'Skyrocket'
Eastern redcedar	Juniperus virginiana	Evergreen; 'Glauca'
Goldenraintree	Koelreuteria paniculata	Very tough summer bloomer
Crape myrtle	Lagerstroemia spp.	Tough summer bloomer
Sweetgum	Liquidambar styraciflua	Fruitless 'Rotundiloba'
Waxmyrtle	Myrica cerifera	Tolerates sandy soil
Colorado spruce	Picea pungens	Monitor for spider mites
Chinese pistache	Pistacia chinensis	Adaptable, pest-resistant
London planetree	Platanus x acerifolia	Tolerates drought
	·	Pest-resistant
Chinese podocarpus Pissard plum	Podocarpus macrophyllus Prunus ceracifera	'Atropurpurea'
Yoshino cherry	Prunus x yedoensis	Monitor for borers
Callery pear (cultivars)	Pyrus calleryana	Avoid 'Bradford'
Laurel oak	Quercus hemisphaerica	'Darlington' for coastal areas only
Willow oak		Tolerates urban conditions
	Quercus phellos	
English oak	Quercus robur	Tolerates drought Tolerates urban conditions
Red oak Live oak	Quercus rubra	Good coastal selection
	Quercus virginiana	Tolerates urban conditions
Japanese pagodatree	Sophora japonica	
American arborvitae	Thuja occidentalis	'Pyramidalis' for form
Oriental arborvitae	Thuja orientalis	Tolerates poor soil
Littleleaf linden	Tilia cordata	'Greenspire'
Silver linden	Tilia tomentosa	Tolerates drought
Lacebark elm	Ulmus parvifolia	Tolerates poor soil, urban conditions
Chastetree	Vitex agnus-castus	Tough summer bloomer
Japanese zelkova	Zelkova serrata	Tolerates poor soil

Some trees, such as Box Elder (*Acer negundo*), Tree-of-Heaven (*Ailanthus altissima*), and Black Locust (*Robinia pseudoacacia*) are heat tolerant and, if found growing on a site, should be considered for use, but otherwise are not considered to be desirable landscape trees due to insect problems and/or invasive growth.
